Biology of adult human microglia in culture: comparisons with peripheral blood monocytes and astrocytes.

Williams K, Bar-Or A, Ulvestad E, Olivier A, Antel JP, Yong VW.

Montreal Neurological Institute, Department of Neurology and Neurosurgery McGill University, Quebec, Canada.

We have compared phenotypic and functional properties of surgically derived adult human microglia to autologous and allogenic peripheral blood-derived monocytes and to astrocytes derived from the same surgical resection. We found that microglia differed from peripheral blood monocytes with respect to adhesion properties and survival rates in vitro. Microglia, similar to resident macrophages in different tissues, expressed many but not all (CD4, Leu-M3, non-specific esterase) monocyte/macrophage associated markers tested, a pattern similar to that of terminally differentiated cells of this lineage. As with other human tissue macrophages, but in contrast to astrocytes, microglia did not undergo DNA synthesis in vitro, assessed using BrdU incorporation. Under basal culture conditions the majority of microglia of all morphologic subtypes (ameboid, bipolar, ramified) expressed MHC class II molecules; by flow cytometric analysis, mean fluorescence intensity of these cells was less than that of blood monocytes (relative to isotype control). In vitro MHC class II antigen expression on microglia, under basal and interferon gamma activating conditions, was greater than on astrocytes. Freshly derived T cells cultured with 1-10% autologous microglia plus Candida albicans underwent active proliferation, indicating the functional capacity of the microglia to serve as antigen-presenting cells.

## Molecular profile of reactive astrocytes--implications for their role in neurologic disease.

Eddleston M, Mucke L.

Department of Neuropharmacology, Scripps Research Institute.

The central nervous system responds to diverse neurologic injuries with a vigorous activation of astrocytes. While this phenomenon is found in many different species, its function is obscure. Understanding the molecular profile characteristic of reactive astrocytes should help define their function. The purpose of this review is to provide a summary of molecules whose levels of expression differentiate activated from resting astrocytes and to use the molecular profile of reactive astrocytes as the basis for speculations on the functions of these cells. At present, reactive astrocytosis is defined primarily as an increase in the number and size of cells expressing glial fibrillary acidic protein. In vivo, this increase in glial fibrillary acidic protein-positive cells reflects predominantly phenotypic changes of resident astroglia rather than migration or proliferation of such cells. Upon activation, astrocytes upmodulate the expression of a large number of molecules. From this molecular profile it becomes apparent that reactive astrocytes may benefit the injured nervous system by participating in diverse biological processes. For example, upregulation of proteases and protease inhibitors could help remodel the extracellular matrix, regulate the concentration of different proteins in the neuropil and clear up debris from degenerating cells. Cytokines are key mediators of immunity and inflammation and could play a critical role in the regulation of the blood-central nervous system interface. Neurotrophic factors, transporter molecules and enzymes involved in the metabolism of excitotoxic amino acids or in the antioxidant pathway may help protect neurons and other brain cells by controlling neurotoxin levels and contributing to homeostasis within the central nervous system. Therefore, an impairment of astroglial performance has the potential to exacerbate neuronal dysfunction. Based on the synopsis of studies presented, a number of issues become apparent that deserve a more extensive analysis. Among them are the relative contribution of microglia and astrocytes to early wound repair, the characterization of astroglial subpopulations, the specificity of the astroglial response in different diseases as well as the analysis of reactive astrocytes with techniques that can resolve fast physiologic processes. Differences between reactive astrocytes in vivo and primary astrocytes in culture are discussed and underline the need for the development and exploitation of models that will allow the analysis of reactive astrocytes in the intact organism.

Production of interleukin-5 by mouse astrocytes and microglia in culture.

Sawada M, Suzumura A, Itoh Y, Marunouchi T.

Division of Cell Biology, School of Medicine, Fujita Health University, Aichi, Japan.

Interleukin (IL)-5 was originally isolated as a B cell growth factor derived from T cells and is known as a multipotent cytokine. We found that IL-5 was detected in the cultures of microglia and astrocytes by both the enzyme-linked immunosolvent assay (ELISA) and bioassay with IL-5-dependent cell line, T88M. We also found that microglia and astrocytes expressed IL-5 mRNA. IL-5 receptor mRNA, however, was not detected in these cells. Stimulation with interferon-gamma increased expression of IL-5 in astrocytes and microglia. These results suggest that IL-5 produced by brain cells may be involved in the interaction between brain cells and immune cells in the brain.

Concurrent isolation and characterization of oligodendrocytes, microglia and astrocytes from adult human spinal cord.

Whittemore SR, Sanon HR, Wood PM.

Miami Project, University of Miami School of Medicine, FL 33136.

A cellular preparation of highly enriched oligodendrocytes was obtained from adult human spinal cord by Percoll gradient centrifugation followed by either differential adhesion or fluorescence-activated cell sorting after immunostaining with an antibody against galactocerebroside (O1). The adherent and O1-negative cell fractions were > 96% microglia. The nonadherent and O1-positive fractions were > 96\% positive for the oligodendrocyte markers O4 and O1, 0-2% positive for glial fibrillary acidic protein, and were devoid of neuronal or microglial markers. If the oligodendrocyte fraction was co-cultured with purified dissociated rat dorsal root ganglion neurons, the oligodendrocytes adhered to the axons and their numbers increased over a 4 week period. However, myelin sheaths were not produced around axons in these cultures. In contrast, if the oligodendrocyte cell fraction was grown alone in culture for > 3 weeks, the number of oligodendrocytes decreased and a layer of astrocytes developed underneath the oligodendrocytes. The oligodendrocytes could be eliminated from these cultures by subsequent passaging, thus producing cultures of pure astrocytes. The astrocytes accumulated both K+ and glutamate with kinetic properties similar to those reported for rodent astrocytes. We suggest that these astrocytes arose in part from an O4/O1-positive precursor which did not initially express glial fibrillary acidic protein. These results define a relatively simple method by which highly enriched populations of oligodendrocytes, astrocytes and microglia can be obtained from adult human spinal cord.

Regulation of interleukin-6 (IL-6) secretion in primary cultured rat astrocytes: synergism of interleukin-1 (IL-1) and pituitary adenylate cyclase activating polypeptide (PACAP).

Gottschall PE, Tatsuno I, Arimura A.

University of South Florida College of Medicine, Department of Pharmacology and Therapeutics, Tampa 33612-4799.

Interleukin-6 (IL-6) is a pleiotropic cytokine that is produced by astrocytes and microglia and may act as a trophic factor in the nervous system. These experiments were intended to identify neuroactive agents that regulate IL-6 production in primary cultured rat astrocytes. Addition of either lipopolysaccharide (LPS) or human recombinant interleukin-1 beta (IL-1 beta) to rat astrocytes in culture stimulated IL-6 secretion. However, LPS was significantly more efficacious in eliciting IL-6 production compared to IL-1 beta. Co-addition of the specific IL-1 receptor antagonist (IL-1ra) completely inhibited IL-1 beta-induced IL-6 secretion but did not affect LPS-stimulated IL-6 production during a 6 h incubation period. Two neuroactive peptides. pituitary adenylate cyclase activating polypeptide (PACAP38) and vasoactive intestinal peptide (VIP), stimulated IL-6 production either alone or in combination with IL-1 beta. PACAP38 was significantly more potent in stimulating IL-6 compared to VIP. Results from these experiments indicate that LPS is an effective inducer of IL-6 production in rat astrocytes. This effect of LPS is independent of astrocyte IL-1 production since the IL-1ra was unable to inhibit LPS-stimulated IL-6 secretion. Also, the neuropeptides PACAP38 and VIP are potential secretagogues for IL-6 secretion, and both peptides synergize with IL-1 to stimulate IL-6 secretion in rat astrocytes.

Infection of human fetal astrocytes with HIV-1: viral tropism and the role of cell to cell contact in viral transmission.

Nath A, Hartloper V, Furer M, Fowke KR.

Laboratory of Neurovirology, Department of Medical Microbiology, Winnipeg, Manitoba, Canada.

Astrocyte cultures from human fetal brain were infected with human immunodeficiency virus (HIV) either as free virus or with a chronically infected lymphoblastoid cell line and monitored for signs of infection. The lymphocytotropic strains HIV3B and HIVSF2(ARV-2) but not the monocytotropic strain HIVAda-M infected the human fetal astrocytes. The infected cells were monitored by immunocytochemistry, detection of p24 antigen in the supernatants and polymerase chain reaction amplification of the proviral DNA. No morphological or cytopathic effects were seen in these cells. Upon co-culture of astrocytes with a lymphoblastoid cell line chronically infected with HIVSF2(ARV-2), the lymphoblastoid cells readily adhered to the astrocytes as determined by a 51Cr adhesion assay and by light and electron microscopy. This cell to cell contact resulted in infection of increased numbers of astrocytes. Similar adhesion of lymphoblasts to microglia was not seen. Thus, astrocytes from human fetal brain can be infected in vitro directly by lymphocytotropic strains of HIV or by adherence to infected lymphoblastoid cells.

FULL TEXT ARTICLE

Microglial ramification requires nondiffusible factors derived from astrocytes.

Tanaka J, Maeda N.

Department of Physiology, School of Medicine, Ehime University, Japan.

It is generally accepted that process-bearing microglial cells origina te from ameboid macrophage-like mesodermal cells. This transformation, often called ramification, accompanies down regulation of macrophage-like properties, but the mechanisms involved in ramification have not been clarified. We investigated factors to promote ramification in culture. Isolated ameboid microglial cells were seeded on living or paraformaldehyde-fixed astrocyte monolayers. About 80% of the cells ramified on the fixed astrocytes in astrocyte-conditioned medium as well as on the living astrocytes. In fresh culture medium, 50% of the cells on the fixed astrocytes ramified. On the other hand, ameboid cells rarely ramified on noncoated glass coverslips even in the conditioned medium. Ameboid cells cultured on extracellular matrices dervied from astrocytes ramified more than on those coated with plasma fibronectin or collagen type I. A synthetic peptide containing Arg-Gly-Asp sequence or a tyrosine kinase inhibitor genistein partially reversed the ramification induced on the fixed astrocyte monolayers. These results show that some nondiffusible factors derived from astrocytes are essential for microglial ramification. A part of the nondiffusible factors are present in the extracellular matrices, and the effects might be mediated by integrins. Some diffusible factors secreted by astrocytes seem to promote ramification, if the nondiffusible factors are present. The experiments using the fixed astrocyte monolayers may be useful to identify the diffusible factors responsibile for ramification.

**1:** Arch Virol. 1997;142(5):1011-9.

Rabies viruses infect primary cultures of murine, feline, and human microglia and astrocytes.

Ray NB, Power C, Lynch WP, Ewalt LC, Lodmell DL.

Laboratory of Persistent Viral Diseases, Rocky Mountain Laboratories, National Institute of Allergy and Infectious Diseases, Hamilton, Montana, USA.

Recent studies have reported the detection of rabies viral antigens and virions in astrocytes and microglia of rabies-infected animals. As a first step toward understanding whether these glial cells may be involved in rabies virus replication, persistence, and/or pathogenesis, we explored their potential to be infected in vitro. Primary cultures of murine, feline, and human microglia and astrocytes were infected with several different rabies viruses: two unpassaged street virus isolates, a cell culture-adapted strain, and a mouse brain-passaged strain. Infection, as determined by immunofluorescence, was detected in 15 of the 16 (94%) virus-glial cell combinations. Replication of infectious virus, determined by infectivity assay, was detected in 7 of the 8 (88%) virus-cell combinations. These results show that astrocytes and microglia can be infected by rabies viruses, suggesting that they may have a potential role in disease, perhaps contributing to viral spread, persistence and/or neuronal dysfunction.

Processing of amyloid precursor protein in human primary neuron and astrocyte cultures.

LeBlanc AC, Papadopoulos M, Belair C, Chu W, Crosato M, Powell J, Goodyer CG.

Department of Neurology and Neurosurgery, McGill University, Montreal, Quebec, Canada.

Increased production of amyloid beta peptide (A beta) is highly suspected to play a major role in Alzheimer's disease (AD) pathogenesis. Because A beta deposits in AD senile plaques appear uniquely in the brain and are fairly restricted to humans, we assessed amyloid precursor protein (APP) metabolism in primary cultures of the cell types associated with AD senile plaques: neurons, astrocytes, and microglia. We find that neurons secrete 40% of newly synthesized APP, whereas glia secrete only 10%. Neuronal and astrocytic APP processing generates five C-terminal fragments similar to those observed in human adult brain, of which the most amyloidogenic higher-molecular-weight fragments are more abundant. The level of amyloidogenic 4-kDa A beta exceeds that of nonamyloidogenic 3-kDa A beta in both neurons and astrocytes. In contrast, microglia make more of the smallest C-terminal fragment and no detectable A beta. We conclude that human neurons and astrocytes generate higher levels of amyloidogenic fragments than microglia and favor amyloidogenic processing compared with previously studied culture systems. Therefore, we propose that the higher amyloidogenic processing of APP in neurons and astrocytes, combined with the extended lifespan of individuals, likely promotes AD pathology in aging humans.
